

Solving Registration Problems on HDI PCBs

Precise Information Within Minutes

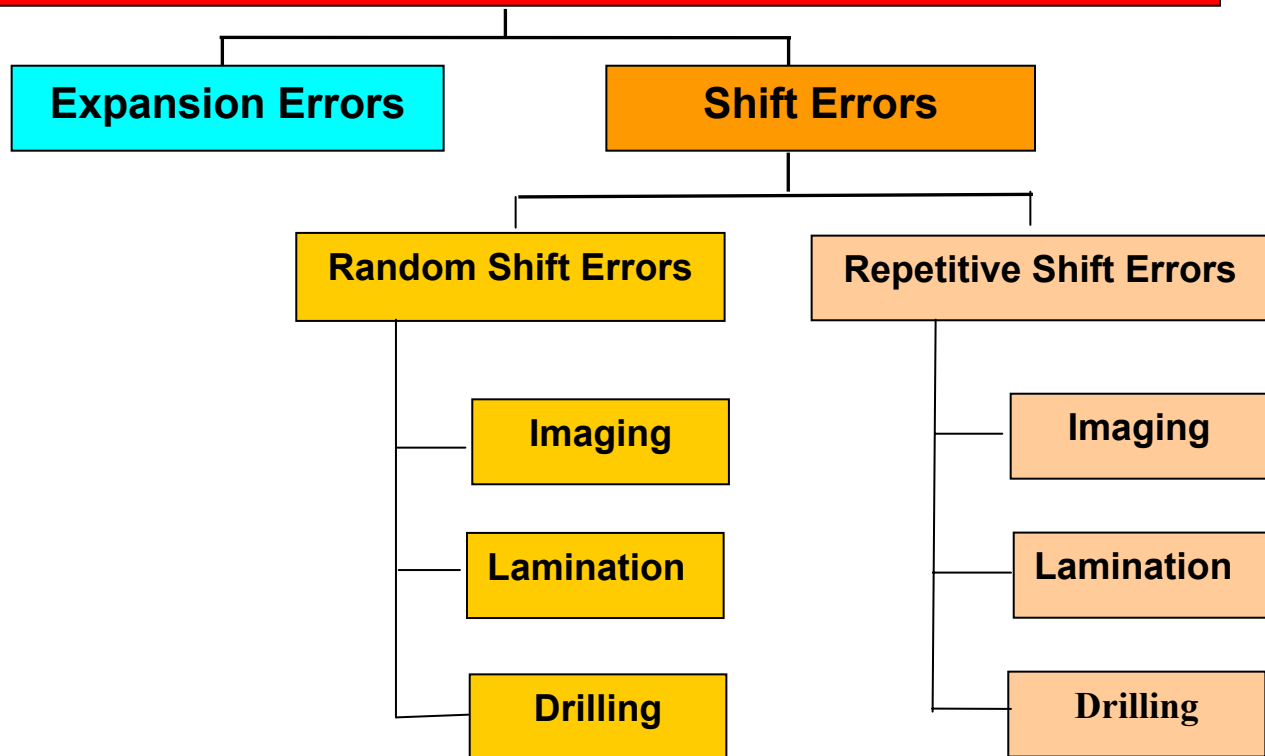

How the System works

Fast Data collection

- Place probe on Coupon in the corners of the panel frame
- Push
- PerfectTest collects data upon contact of probe pins with coupon, instantly, accurately
- Non destructive test
- High throughput: up to six panels per minute
- Collect precise registration information from HDI PCBs of any construction.

Causes of Registration Errors

Registration Errors are always a combination of different causes

Separate the Causes of Registration Errors

- Expansion errors occur when inadequate scaling factors are applied to the artwork. Expansion registration errors are job specific. They describe the size of layers of a specific job. Depending on materials, panel constructions, and fabrication processes, necessary scaling factors will differ with each job.
- Shift Errors describe the location of inner layers, cores, or panels during the fabrication process. Shift errors are caused by tooling inaccuracies or operator errors. Shift error patterns are typically repeated on different jobs.
- Expansion errors are corrected with better scaling factors.
- Shift errors are corrected with tooling adjustments and improved operating procedures.

Panel Construction Entry

Construction: Foil
Total layers: 10

Select Parameters Add Layer Add Core Add Pre-Preg Delete Move Field Up Down
